ABSTRACT

Objectives: Acute sinusitis accounts for up to 82% of orbital infection cases. Infection spreads very quickly, especially through the ethmoid sinus, and orbital complications may arise even under antibiotic therapy. The aim of this study was to describe an 8-year hospital experience with these children.

Methods: All cases of acute sinusitis with orbital complications admitted to the Department of Otorhinolaryngology of Centro Hospitalar e Universitário de Coimbra between 2010 and 2017 were retrospectively reviewed.

Results: Sixty-four patients met the inclusion criteria, with a mean age of 9 ± 4.7 years. Male:female ratio was 1.67:1. Most subjects were admitted in the winter period (57.8%), with 2.9 ± 2.5 days of clinical evolution. The mean Lund Mackay score was 10.6 ± 4.9, with maxillary and ethmoid being the most prevalent involved sinuses (96.4% and 94.6%, respectively), and was inversely correlated with age (p<0.05). Preseptal cellulitis was the most common complication (56.3%). Abscesses were identified in 18.7% of patients, but only four (6.25%) required surgery. Seven cases (10.9%) recurred shortly after hospital discharge and required prolonged antibiotic course. All patients recovered well, without further complications.

Conclusion: Results showed that orbital complications of sinusitis respond well to high doses of endovenous antibiotherapy and patients tend to recover without local comorbidities. Close monitoring of these patients during the first months after hospital discharge is crucial to prevent early relapse.

Keywords: complications; orbital disease; sinusitis

RESUMO

Objetivos: A sinusite aguda é responsável por até 82% dos casos de infeções orbitárias. As infeções propagam-se facilmente, em particular através das células etmoidais, mesmo em crianças sob antibioterapia. O objetivo deste estudo foi descrever a experiência de oito anos de um centro hospitalar com esta patologia.

Métodos: Revisão retrospectiva dos casos de sinusite aguda com complicações orbitárias admitidos no Departamento de Otorrinolaringologia do Centro Hospitalar e Universitário de Coimbra entre 2010 e 2017.

Resultados: Sessenta e quatro doentes foram incluídos no estudo, com uma idade média de 9 ± 4,7 anos e uma proporção de rapazes:raparigas de 1,67:1. A maioria dos doentes foi internada nos meses de inverno (57,8%), com 2,9 ± 2,5 dias de evolução clínica. O score de Lund Mackay foi de 10,6 ± 4,9, com os seios maxilar e etmoidais mais prevalentemente envolvidos (96,4% e 94,6%, respectivamente), e correlacionou-se...
INTRODUCTION

Acute sinusitis is responsible for up to 82% of cases of orbital infection. Before the widespread use of antibiotherapy, 17% of patients affected by orbital cellulitis died from meningitis and 20% suffered permanent visual loss. Orbital complications can occur either directly through a defect in the lamina papyracea or from an septic emboli. Diagnosis is usually established through the combination of clinical examination and radiologic findings. Chandler’s classification, published fifty years ago, still represents the most complete and popular classification of orbital infection severity. The best pharmacological modality for these patients remains controversial, and the optimal surgical approach has been debated, especially since the widespread use of endoscopic nasal surgery. The aim of this study was to analyze the outcomes of patients admitted to the Department of Otorhinolaryngology of our institution with orbital complications due to acute sinusitis over an eight-year period.

RESULTS

A total of 64 children were admitted to our hospital department between 2010 and 2017, with a mean age of 9 ± 4.7 (range 1-17) years and predominantly (62.5%) male. Most patients were admitted during winter months (57.8%) and 65.6% were not under any medication on admission. Clinical findings are resumed in Table 3. Most patients were admitted with rhinorrhea (78.1%) and only 46% presented with fever. Patients with rhinorrhea tended to be admitted earlier to the Emergency Department compared with patients without this symptom (2.6 vs. 4 days, respectively; p=0.05). Ocular signs were uncommon, with ocular pain being the most relevant ophthalmologic sign (31.8%), followed by ophthalmoplegia, diplopia, and proptosis. Computed tomography (CT) scan was performed in 65 (87.5%) patients, with ethmoidal and maxillary being the most commonly affected sinuses (95.6% and 96.4%, respectively). Frontal disease was more prevalent in older patients (11.0 ± 4.0 vs. 7.9 ± 4.2; p=0.01). Lund-Mackay score was used for sinusitis radiologic staging, showing a mean value of 10.6 ± 5.0 (range 3-23) and inverse correlation with age (p=0.01). Most (53.8%) patients with proptosis on admission presented abscesses in CT scan (p=0.001). Laboratory findings showed a mild rise in white blood cells (15.5 ± 4.0 x 10^9/L) and C-reactive protein (10.5 ± 9.0 mg/L).

Cellulitis was the most prevalent complication in this patient population (Table 5). Thirty-six patients (56.3%) developed preseptal cellulitis, and 60 patients (93.8%) presented orbital cellulitis. Three patients (4.7%) required surgical intervention. Sete (10.9%) cases occurred logo após a alta hospitalar and exigiam antibioterapia prolongada. Todos os doentes recuperaram bem, sem lesões sequelares.

Conclusão: Os resultados obtidos demonstram que as complicações orbitárias da sinusite respondem bem à terapêutica médica e os doentes frequentemente recuperam sem comorbididades locais. O acompanhamento clínico destes doentes durante os primeiros meses após a alta hospitalar é essencial para evitar recidivas precoces.

Palavras-chave: complicações; doença orbital; sinusite

MATERIAL AND METHODS

A retrospective review of medical records of all children (age <18 years) diagnosed with orbital complications of acute sinusitis admitted to our hospital department between 2010 and 2017 was conducted. Data retrieved included demographics, clinical signs and symptoms, laboratory study, radiologic evidence of orbital inflammation and sinusitis, treatment with intravenous antibiotic, and surgical intervention. Stata® 15.0 was used for data descriptive and analytical statistics. Associations between dichotomic variables were assessed with chi-squared test (or Fisher’s exact test, when applicable), and continuous measures were compared using a two-sample student t-test. Statistical significance was set at 0.05.
(Chandler type I) and 16 patients postseptal (Chandler type II) cellulitis. Overall, 12 patients (18.8%) presented subperiosteal
(n=7) or orbit (n=5) abscesses. Two patients with orbital abscesses
developed intracranial complications: cerebral abscess in one patient
and cavernous sinus thrombosis in another patient.

Treatment predominantly included high doses of intravenous
ceftriaxone combined with other drugs (flucloxacilin, clindamycin,
or metronidazole; Table 6). Sixty-one (95.3%) patients received
concomitant intravenous corticotherapy. Patients exclusively treated
with medical therapy had a lower mean age (8.75 ± 4.8 years;
p>0.05). Only four patients, with a mean age of 12.8 ± 3.0 years,
required surgical drainage, three of whom with external approach
and one with combined approach. Two of these patients presented
positive culture, one for Fusobacterium necrophorum and the other
for Streptococcus constellatus. The mean length of hospital stay was
8.0 ± 5.5 days (range 2-38), and was longer in patients submitted
to surgery (11.3 ± 2.9 vs. 7.8 ± 5.6 days in patients undergoing
pharmacotherapy, p>0.05) and in older patients (R=0.2546, p= 0.04).

Seven patients (10.9%) recurred shortly after hospital discharge
(mean 10.6 ± 7.3 days) due to relapse of orbital signs and were
submitted to a longer period of parenteral antibiotherapy, with full
recovery. Programmed adenopectomy was performed in two of
these patients (with five and eight years, respectively), and functional
endoscopic sinus surgery was performed in a 13-year-old patient to
improve nasal breathing.

Management of these patients remains a critical issue. Several studies reported a high percentage of patients successfully treated with medical therapy only,\textsuperscript{4,11,14,16,17} in agreement with findings from this study. Parenteral therapy should include broad-spectrum agents, with some authors recommending maintaining it for up to 2–3 weeks.\textsuperscript{18} Itzhak Brook recommended an association with a beta-lactam/beta-lactamase inhibitor (e.g., ampicillin-sulbactam, amoxicillin-clavulanate, piperacillin-tazobactam), a carbapenems (e.g. imipenem, meropenem), or a third-generation cephalosporin (e.g. ceftriaxone, cefotaxime) and metronidazole or clindamycin to cover anaerobic bacteria.\textsuperscript{19} In this study, patients were preferentially treated with high doses of ceftriaxone, associated with metronidazole or clindamycin in cases of high suspicion of abscess.

Improvement can be assessed by clinical (decrease of ocular edema, erythema, and discomfort) and laboratory progress, with serial CT scans not recommended, for not being a reliable indicator of clinical improvement.\textsuperscript{5,9,12} In this study, all patients requiring surgery were above nine years of age. However, results in the literature remain inconclusive regarding age as a potential risk factor for surgical therapy. The odds ratio for requiring surgical treatment increase by 1.5 with each year of age above 5 (\(p=0.004, 95\% \text{ CI } 1.33-1.89\)), according to Todman MS and colleagues.\textsuperscript{12,15} Management of these patients remains a critical issue. and other stages usually require surgical approach to clear the purulent collection. Regular evaluation of these patients is critical, as failure to improve after the first 48 hours likely reflects treatment failure and need for surgical intervention.

CONCLUSION

This eight-year experience indicates that early diagnosis and prompt institution of appropriate intravenous antibiotic therapy in hospitalized children with orbital complications of acute sinusitis can lead to favorable clinical outcomes without surgical intervention in most children. All patients should be closely monitored with serial ophthalmologic examination, and any deterioration should lead to timely drainage.
